Multi-User Detection for Next-Generation CDMA:Final Report

Final Progress Report

- (1.) Statement of the problem studied**
- (2.) Summary of the most important results**
- (3.) Listing of all publications and technical reports**
- (4.) List of all participating scientific personnel showing any advanced degrees earned by them while employed on the project**

DISTRIBUTION STATEMENT A
Approved for Public Release
Distribution Unlimited

(1.) Statement of the problem studied

The overall objective of this grant was to investigate basic research issues on signal processing for demodulation of multiuser digital wireless communication systems of interest to future U.S. Army terrestrial tactical needs. This study motivated by the emergence over the past years of the field of multiuser detection from previous ARO-sponsored projects led by the principal investigators.

A major goal of this project was to design and analyze detectors that could be used with long-sequence CDMA. This is the Direct-sequence method employed in several civilian and military spread spectrum systems. To that end, random spreading models are used to obtain succinct figures of merit based on congestion and bandwidth.

(2.) Summary of the most important results

i. Fast adaptive algorithms for linear and nonlinear multiuser detection based on new scalable architectures.

ii. A new iterative algorithm whose parameters have been obtained analytically using the theory of asymptotic distribution of eigenvalues of random matrices.

iii. Using random matrix models, we have been able to obtain a general method to analyze the fundamental limits of multiuser detectors when used with error control codes and randomly spread CDMA. The designer of a CDMA system can use this method to obtain the optimum coding redundancy/ spreading gain tradeoff. show that the spectral efficiency of CDMA can be multiplied by a factor of roughly 4, by increasing receiver complexity and by increasing the number of users per chip from 1/4 (typical of current systems) to 2.

iv. A general formula which for an arbitrary fading distribution, number of users to spreading gain ratio, and signal-to-noise ratio quantifies the gain in spectral efficiency achievable by optimum nonlinear processing over optimum linear processing.

v. Transmitter Power control strategies that adjust transmitted power as a function of the individual slow-fading level in order to maximize spectral efficiency.

vi. In the case of Rayleigh fading, and for any energy per bit we have shown that optimum transmitted power control enables the spectral efficiency to be unbounded as the number of users and the receiver complexity increases.

vii. Analysis and design of multiuser detectors in eavesdropping environments where there are large power imbalances between desired and interfering users.

(3.) Publications and technical reports supported under this grant or contract.

(4.) Participating Scientific Personnel

Principal Investigator:

Sergio Verdú

Postdoctoral Fellows:

Ralf Mueller

Antonia Tulino

Graduate Students:

Andrew McKellips (PhD August 1999)

Linbo Li

Dongning Guo

Jan Bacsy (PhD August 1999)
